Geological Survey (in Land Area) Made at the Kashiwazaki Kariwa Nuclear Power Station after the Occurrence of Niigata-Chuetsu-Oki Earthquake

1. Objectives

Following the occurrence of Niigata-Chuetsu-Oki Earthquake on July 16, 2007, the Tokyo Electric Power Company, Inc. (TEPCO) decided to make a subsurface exploration at the site of Kashiwazaki Kariwa Nuclear Power Station (NPS) and its adjoining area by expanding the scope of the geological survey for seismic safety assessment which had been conducted since last year to appropriately reflect the knowledge obtained through this earthquake in its evaluation of earthquake safety at the Nuclear Power Station. This subsurface exploration will cover the extensive land area encompassing the Nagaoka Plain Western Rim Fault Zone in addition to the immediate land area adjoining the NPS, and active faults in the area will be checked and evaluated again by understanding the underground geological structures through the subsurface exploration, etc.

Boring and other surveys will also be performed at the NPS site to compare the results of the subsurface exploration with those of the geological survey. Boring surveys as well as the physical testing of samples collected from the bedrocks under the foundations of the reactor facilities after the earthquake also will be conducted in the NPS site to appropriately reflect the knowledge obtained from the physical characteristics of the bedrocks in the seismic safety assessment of the NPS.

We plan to conduct additional boring and other surveys in the NPS site in order to check the properties of the ground there and evaluate the land subsidence and soil liquefaction risks, and we'll set about these surveys as soon as the preparatory arrangements for them are completed.

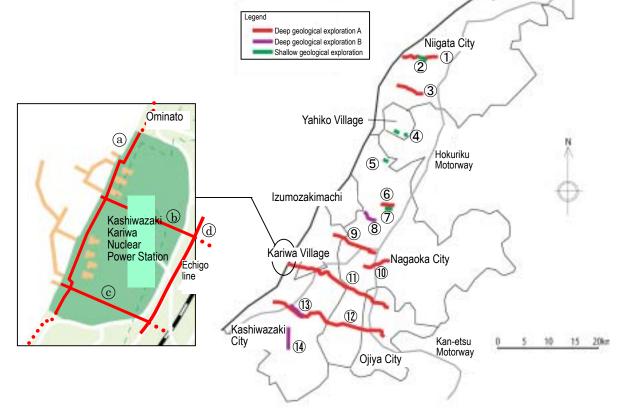

2. Locations of surveys

(1) Area around the NPS

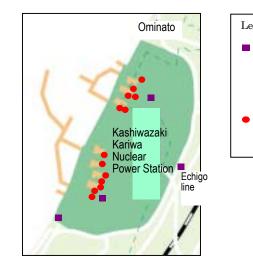

- Subsurface exploration: The land area from the north part of Niigata Prefecture through the area around the NPS with 14 survey lines at the total length of about 100km
- (2) The NPS site and its adjoining area
- Subsurface exploration: Approx. $3 \text{km} \times 1$ survey line ((a)) and approx. $2 \text{km} \times 1$ survey line ((b)) in the south-north direction Approx. $2km \times 2$ survey lines ((b) and (c))

Approx. 17 points

Survey lines (projected) for subsurface exploration

3. Periods of surveys

			Geologic	a	S	ur	ve	y S	Scl	hec	lule		
Location of survey			Survey method	Sept.						Oct.			
Lood of of Survey				10		20	3	0	10	20			
NPS site and its adjoining area	а	Kariwa Village, Kashiwazaki City	Deep geological exploration A Earthquake simulation vehicle A × 2 units										
	b∼d												
Survey of land area around the NPS	1	Nishiura-ku, Niigata City	Deep geological exploration A Earthquake simulation vehicle A × 4 units										
	3	Nishiura-ku, Niigata City	Deep geological exploration A Earthquake simulation vehicle A × 4 units						I				
	6	Nagaoka City	Deep geological exploration A Earthquake simulation vehicle A × 1 unit						T				
	10	Nagaoka City	Deep geological exploration A Earthquake simulation vehicle A × 1 unit										
	Other survey lines	Ojiya City; Kashiwazaki City; Kariwa Village; Nagaoka City; Yahiko Village	Earthquake simulation vehicle A Earthquake simulation vehicle B Earthquake simulation vehicle C								00		
Boring survey													

* The Survey schedule may be changed depending on the results of the consultations with the organizations concerned and others.

September 13, 2007 The Tokyo Electric Power Company, Inc. Kashiwazaki Kariwa Nuclear Power Station

Legend

- Boring surveys conducted to compare the results of the subsurface exploration with those of the geological survey (at 4 points at the depths of about 300m to 1300m)
- Boring surveys for bedrocks (at 13points at the maximum depth of about 300m)

4. Survey methods

(1) Subsurface exploration

The subsurface exploration is a survey technique in which an earthquake simulation vehicle is used to give small vibrations to the ground (or road) and determine their ways of propagation by means of small seismometers placed on the edges (or shoulders) of the road in order to evaluate the underground geological structures. In this time, we'll make the "deep geological exploration A" up to the maximum depth of about 4km by using plural earthquake simulation vehicles A, the "deep geological exploration B" up to the maximum depth of about 500m by using plural earthquake simulation vehicles B, and the "shallow geological exploration C" up to the maximum depth of about 100m by using plural earthquake simulation vehicles C. These earthquake simulation vehicles will move on the road in turn to make measurements in the projected sections of the road.

Main equipment (for shallow Main equipment (for deep geological exploration) geological exploration) • Earthquake simulation vehicle A Earthquake simulation vehicle B • Earthquake simulation vehicle C Total width: 1.9m Total length: 4.8m Total width: 1.5m (or 3m with arm lifted) Total width: 2.4m Total length: 8.2m Total length: 3.5m Total height: 2.4m Weight: 2.0t Total height: 3.3m Weight: 17.7t Total height: 2.8m Weight: 6.5t Planting and othe Observation vehicle Earthguake simulation Seismometers Reflected waves Vibrations Reflection plane (boundary face)

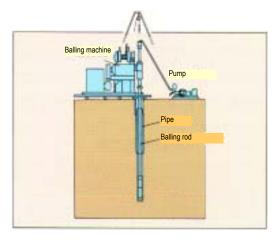

Principle of earthquake exploration by reflection method

(2) Boring survey

Samples as rod type cores are continuously collected from bedrocks and observed to evaluate their geological characteristics.

(3) Physical testing on bedrocks

The samples collected by boring surveys from bedrocks are tested in strength and hardness by using various methods such as giving stresses to them and transforming them
